# この講義の目標

1. ハドロン物理学の基本的知識を理解して用語を説明できること
2. ハドロン現象論の基本的なモデルの特徴を理解しうて説明できること
3. エキゾチックハドロンの性質について実験データあるいは理論に基づいて説明できること

## 日本物理学会創立70周年記念企画

? 70

## 物理学の不思議

16. 原子核の形 19. 格子QCD 5. 素粒子の世代  
 13. 陽子ニクオーネ3つ? 11. ヒッグス粒子 37. 素粒子と物性 36. 量子コンピュータ  
 14. テトラクオーネ 18. 原子核の地図 6. ニュートリノ 38. モンテカルロ計算 53. フュルミ液体論  
 17. 超重原子核 10. クオーケの閉じこめ 39. マヨラナ粒子 45. 光誘起相転移 41. トポロジカル秩序  
 4. クオーケ・グルーオン・プラズマ 26. 磁場の起源 49. 物質設計 30. 乱流 44. メタマテリアル  
 15. ストレング原子核 8. 暗黒エネルギー 34. 量子力学の検証 55. 隠れた秩序  
 12. 反物質 7. 暗黒物質 1. 宇宙のはじまり 48. 極限環境 46. 界面  
 21. 中性子星 2. 4次元時空 3. インフレーション 31. 量子電磁力学 52. 銅酸化物高温超伝導  
 33. 冷却原子 29. 核融合 20. 恒星 50. 金属と絶縁体 57. 統計力学の基礎  
 9. 宇宙の物質生成 27. 太陽コロナ 60. ガラス 58. 非平衡状態 47. スピントロニクス  
 24. 相対論的ジェット 56. 量子と古典 54. スピノ・軌道相互作用 59. 可積分系  
 22. 超大質量ブラックホール 65. タンパク質 32. 原子時計 43. 超短パルスレーザー<sup>?</sup>  
 25. 宇宙線 35. 量子通信 67. 分子機械 61. 動体 63. 生物の運動 42. 観るの極み  
 23. ブラックホールと情報 67. 分子機械 61. 動体 63. 生物の運動 42. 観るの極み  
 70. 物理学はどこへ? 34. シマウマの縄 66. 電子と生命 40. 還元と創発  
 62. 経済物理 69. 私たちと物理 68. 物理と生命

# 内容

## 1. イントロダクション

1.1 ハドロンの基本的性質

1.2 なぜ重いハドロンを研究するのか？

## 2. 重いクォークのスピン対称性と有効理論

2.1 スpins対称性とハドロンスペクトロスコピー

2.2 重いクォークの有効理論

2.3 重いハドロンの有効理論

## 3. 重いエキゾチックハドロン -ハドロン相互作用の観点から-

3.1 なぜエキゾチックハドロンが面白いのか？

3.2 チャームメソン :  $X, Y, Z_c$

3.3 ボトムメソン :  $Z_b$

3.4 チャームペンタクォーク :  $P_c, P_{cs}$

3.5 ダブルチャームメソン :  $T_{cc}$

3.6 フルチャームメソン :  $X_{cc}$

3.7 反応論—重イオン衝突によるエキゾチックハドロン生成—

# 1. Introduction

基本問題

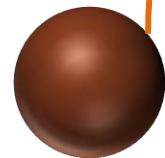

核子間に働く力(核力)とは?

# 1. Introduction

## 電気力と核力の性質の違い

電気力

陽子

電子

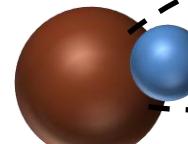

光子(フォトン)の交換

- ・ほどほど強さ( $\alpha=1/137$ )
- ・無限に遠くまで届く

核力

湯川秀樹  
(1907-1981)

陽子

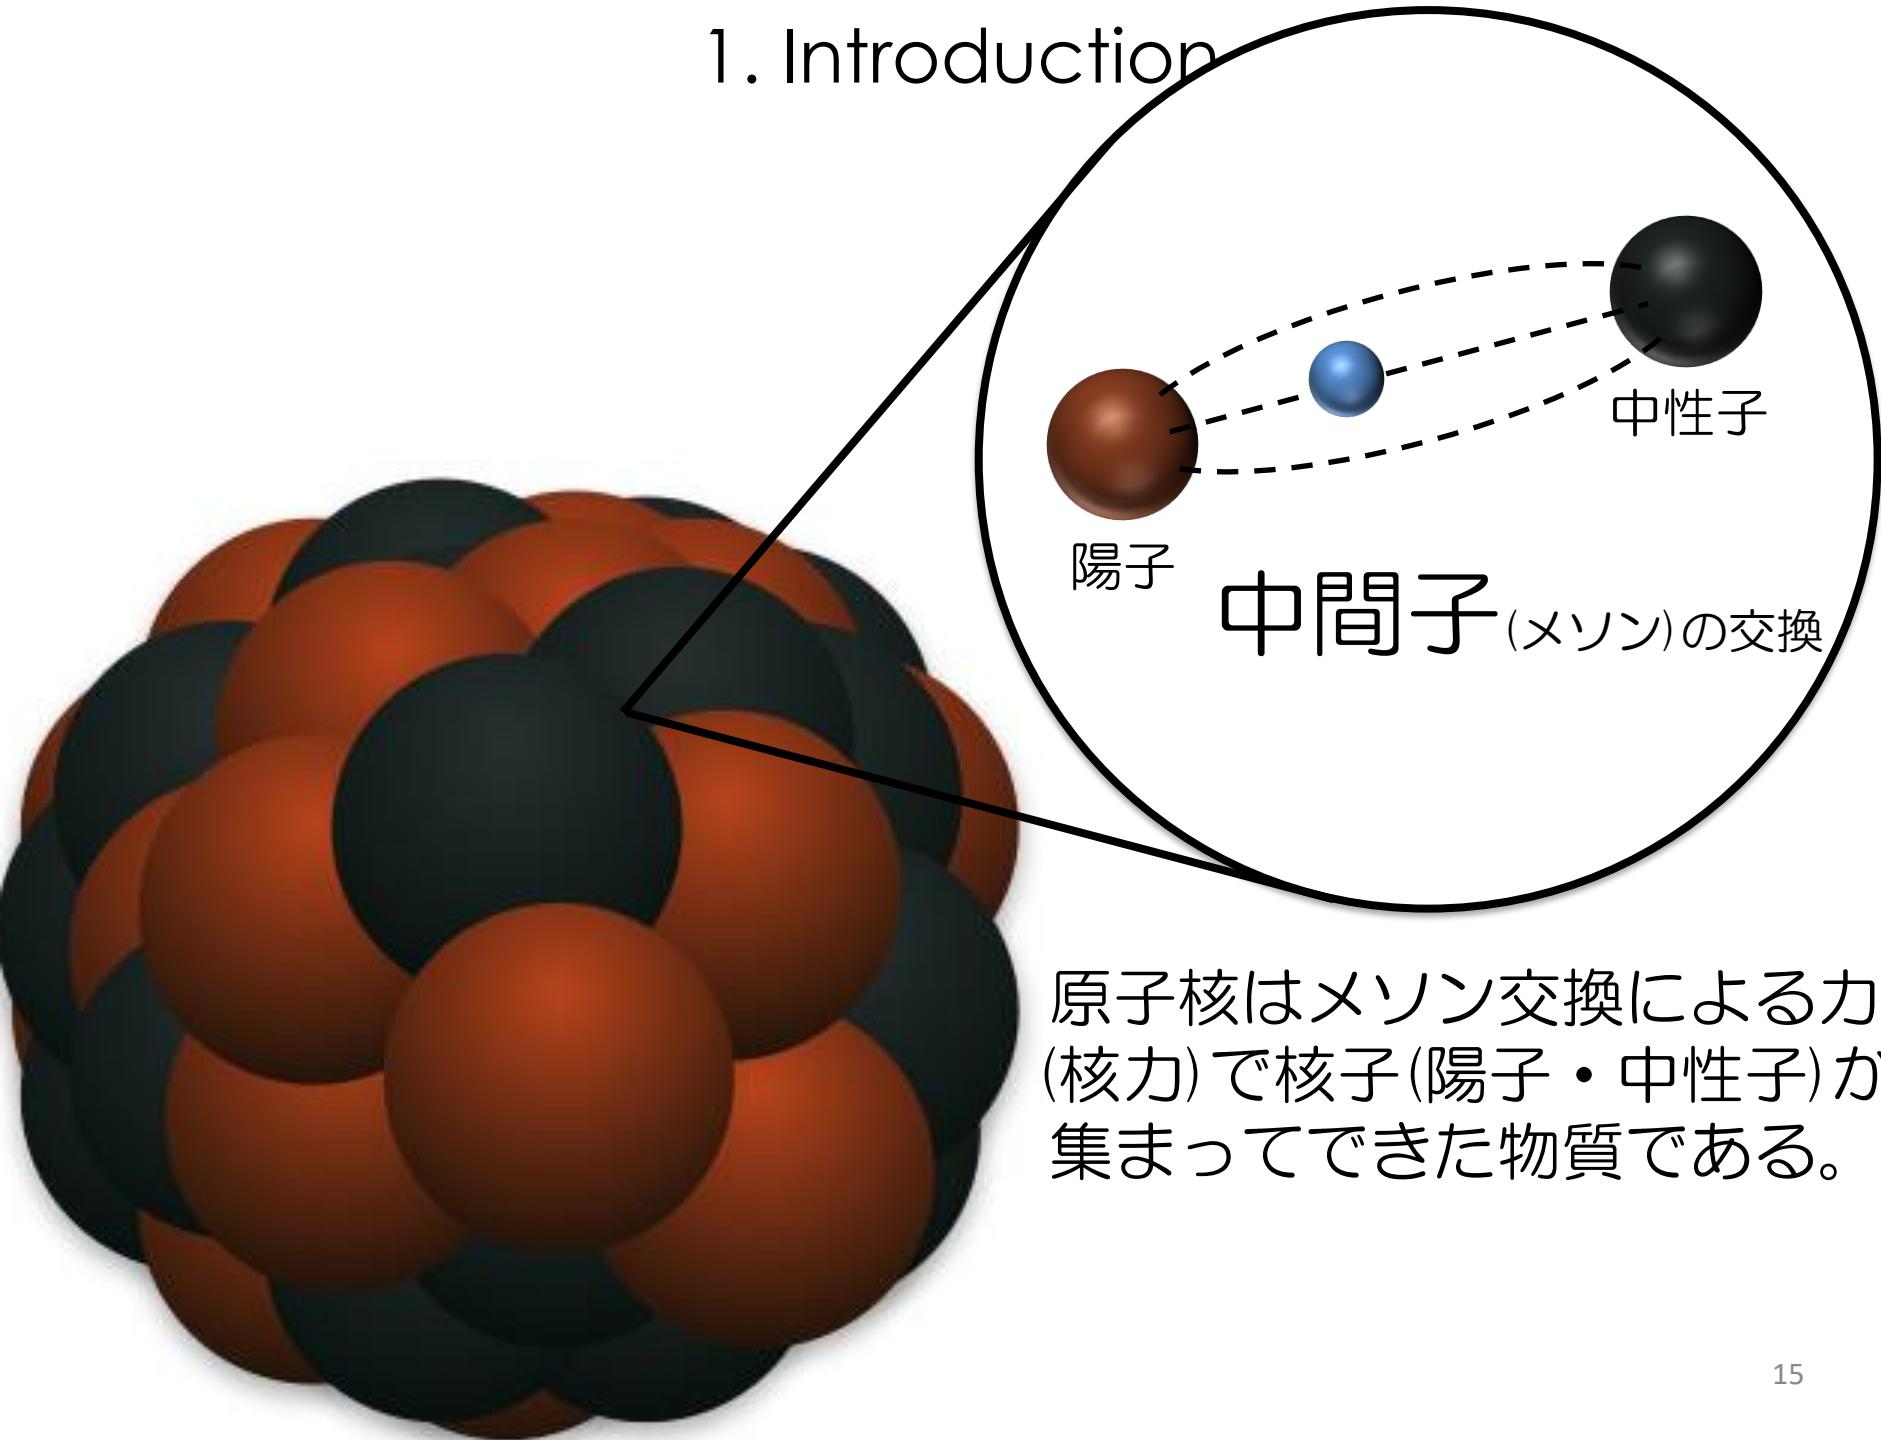

中性子

中間子(メソン)の交換

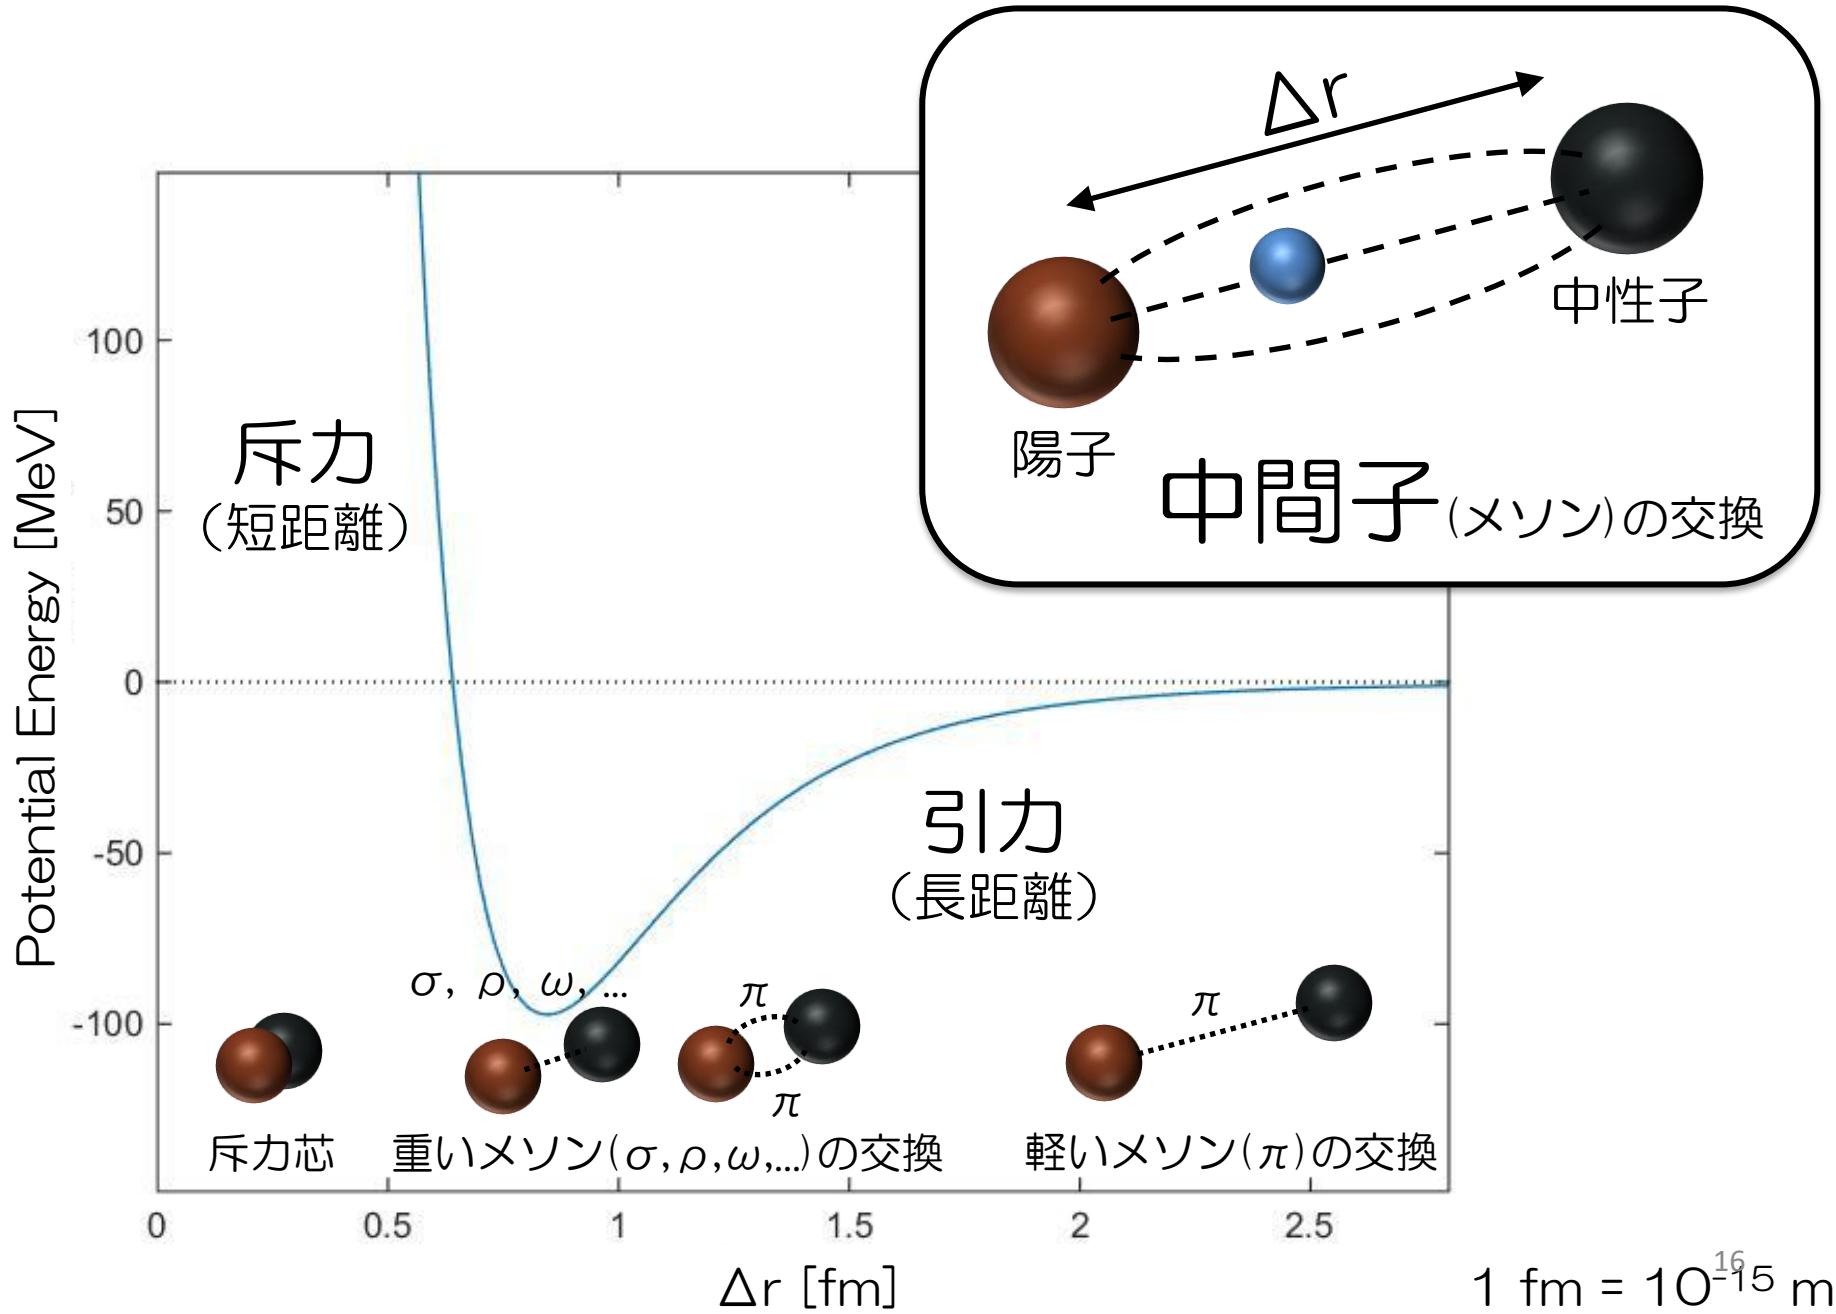

- ・かなり強い(電気力の100倍以上)
- ・短い距離しか届かない(数fm以下)

# 1. Introduction

原子核はメソン交換による力  
(核力)で核子(陽子・中性子)が  
集まってできた物質である。

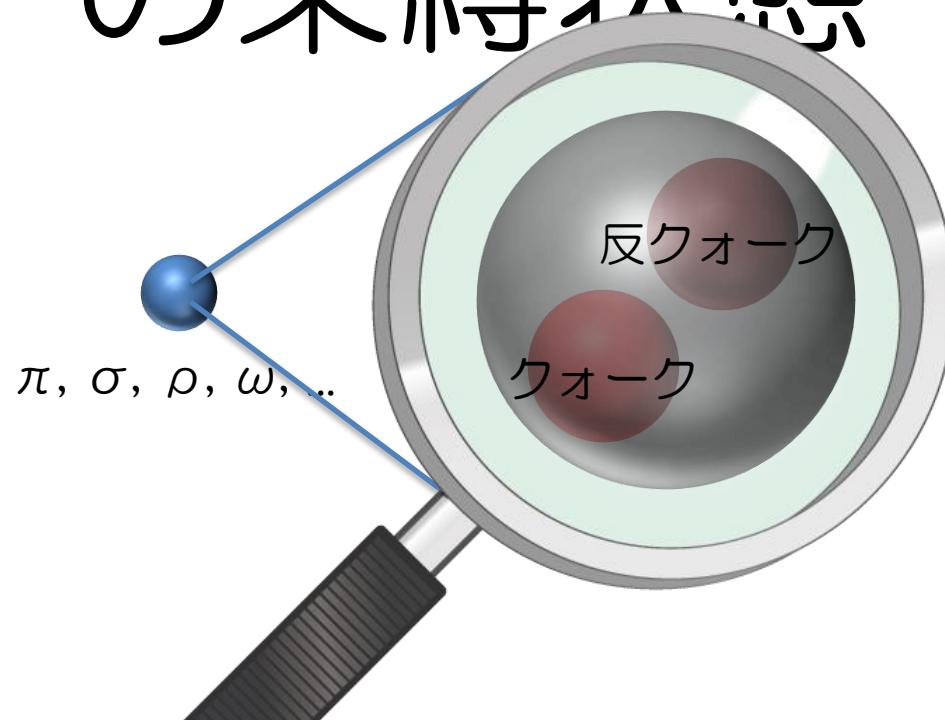

# 1. Introduction

Can we understand nucleus/hadron by quarks and gluons?

# 1. Introduction Questions

- How do quarks compose hadrons?

quarks

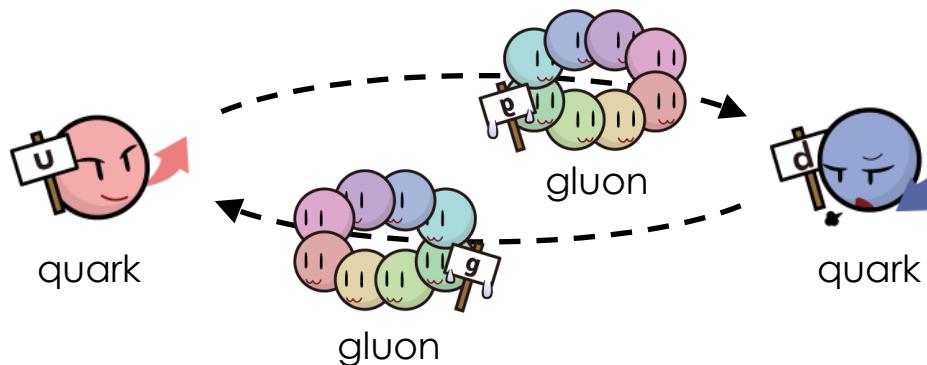

hadrons

# 1. Introduction

How do quarks move?

$$ma = F$$

# Gluon

HiggsTan.com

# 1. Introduction

“Law of motion” of quarks and gluons

# Quantum Chromodynamics (QCD)

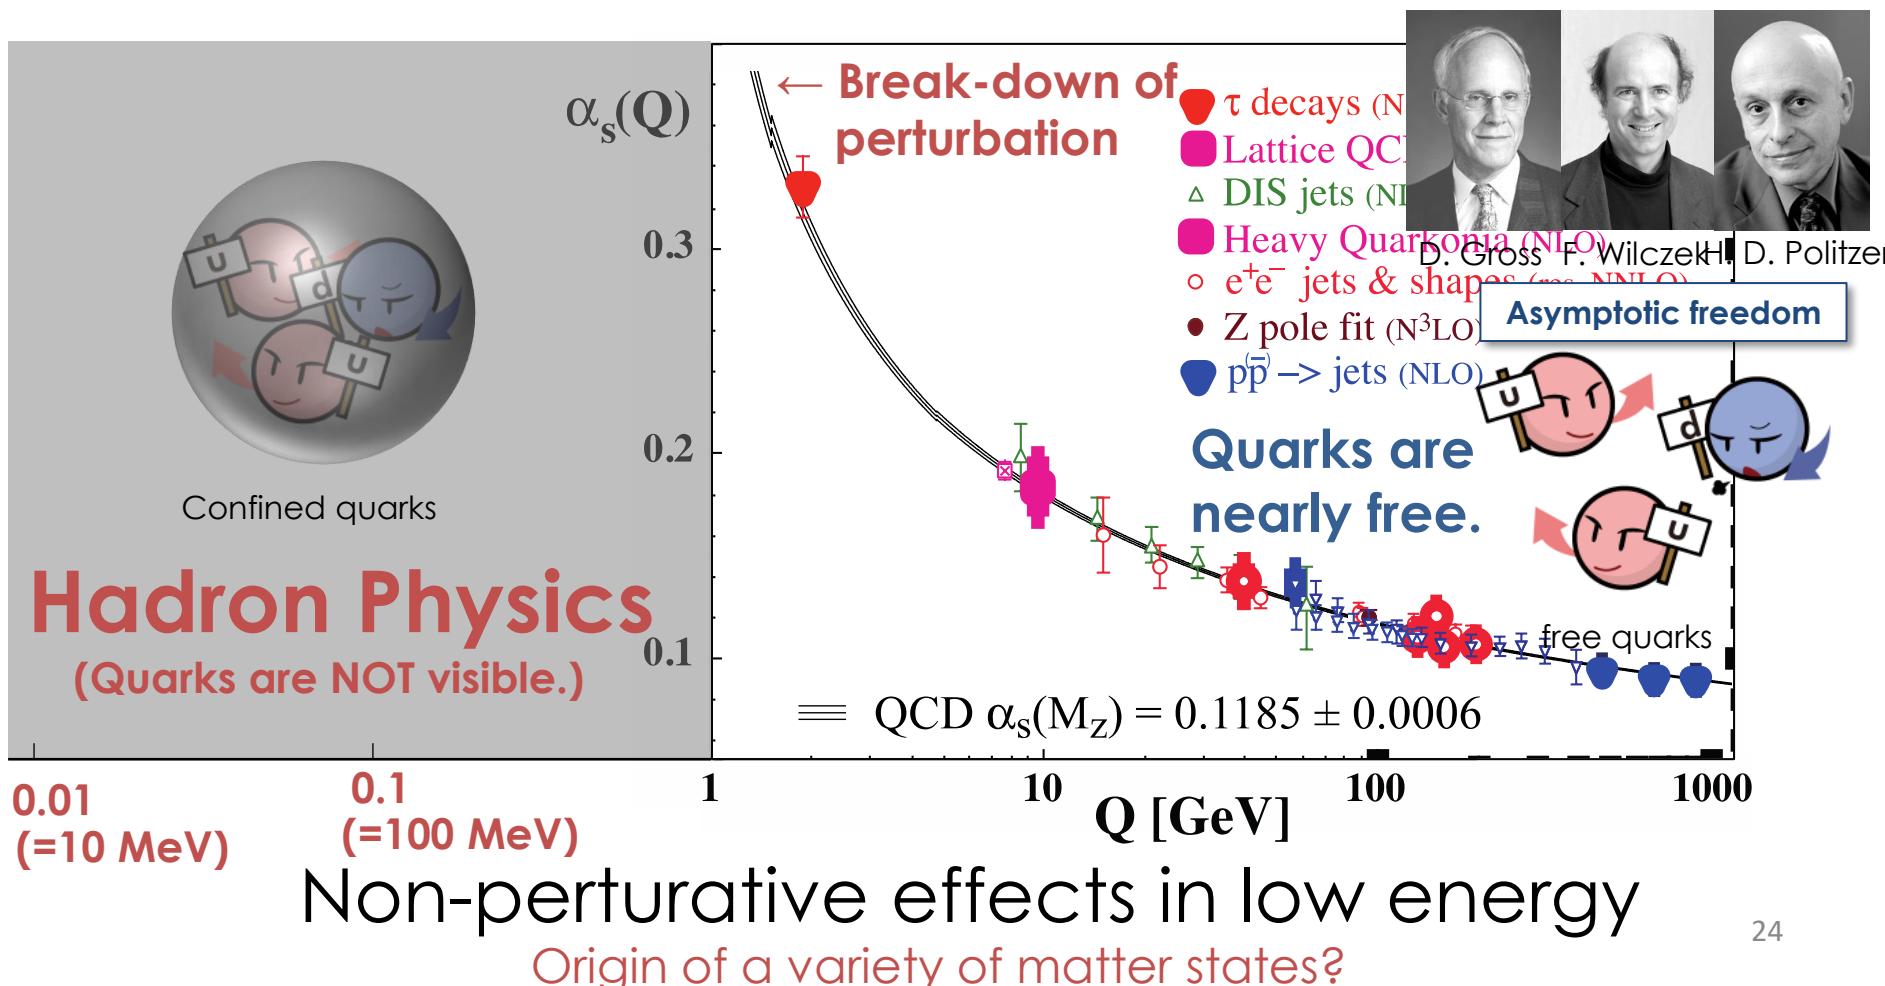

$$\mathcal{L}_{\text{QCD}}[\bar{\psi}, \psi, A] = \sum_f \bar{\psi}_f (i\cancel{\partial} - g_s A_\mu - m_f) \psi_f - \frac{1}{4} F_{a\mu\nu} F^{a\mu\nu}$$

$\psi_f$ : quark field (flavor  $f$ )       $g_s$ : coupling between  
 $A_\mu, F_{\mu\nu}$ : gluon field      quarks and gluons

# 1. Introduction

## Why is hadron physics difficult?

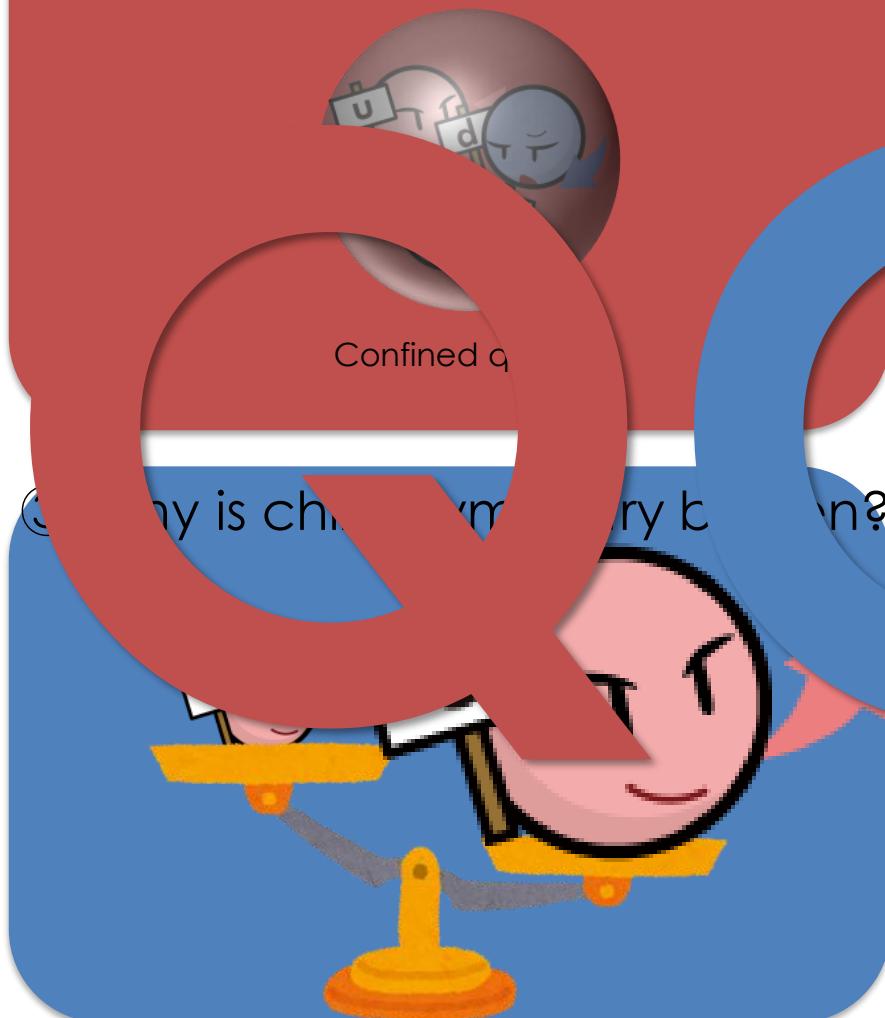

Answer: *strong coupling in low energy*

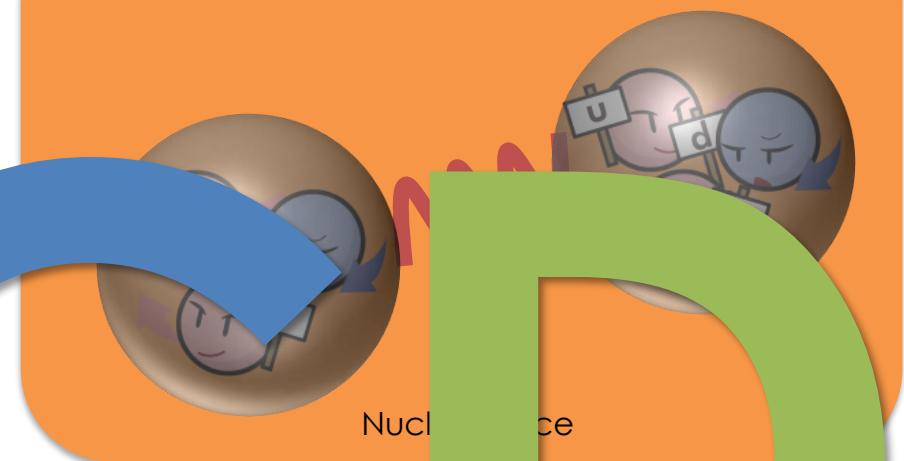

# 1. Introduction

## Fundamental 4 Questions in Hadron Physics

① Why are quarks confined?

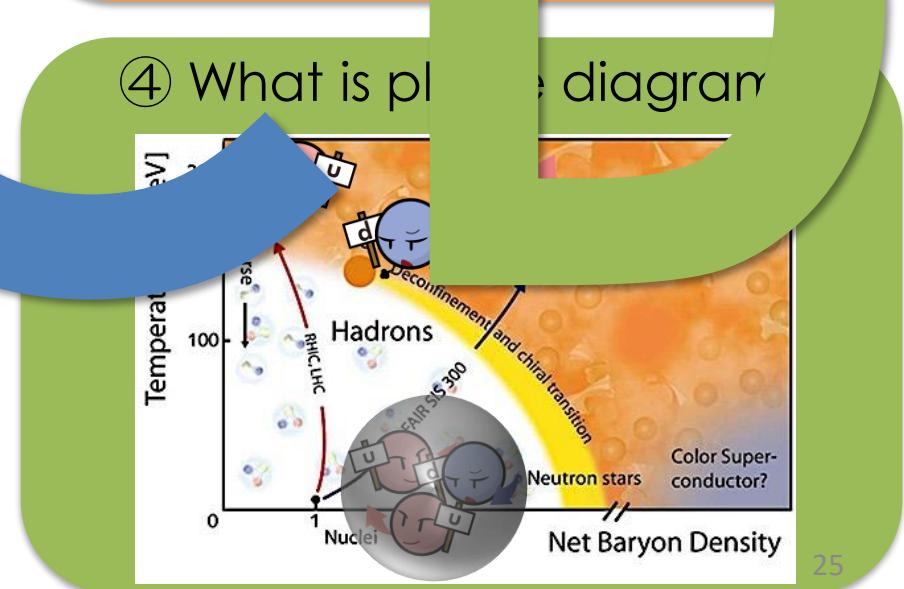

② What is hadron interaction?

③ Why is chiral symmetry broken?

④ What is phase diagram?

# 1. Introduction

## Properties of QCD

① Color charge (red, blue, green)

# 1. Introduction

## Color charge (review)

QED  
U(1) symmetry  
electron  $e^-$

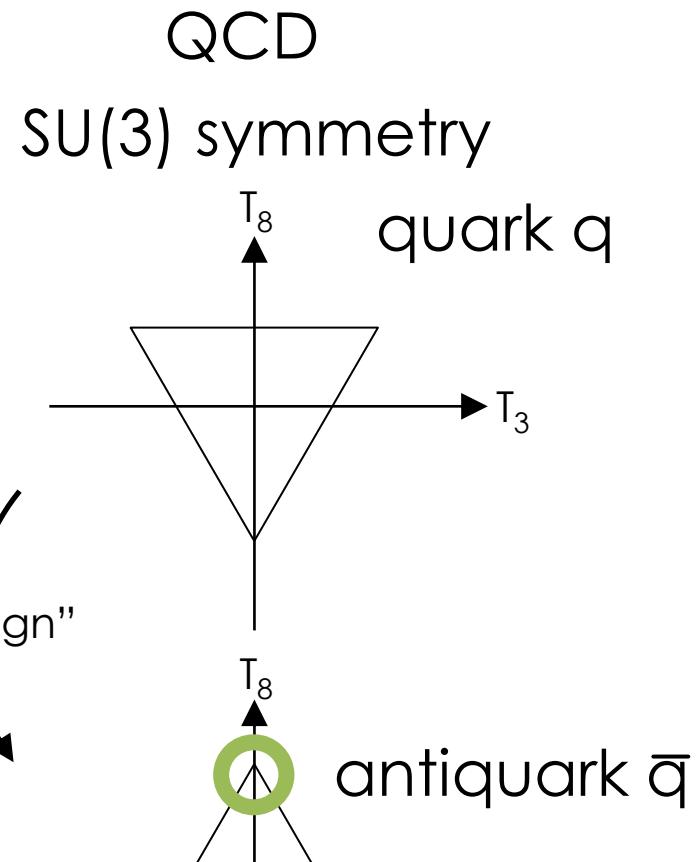

$-e$

positron  $e^+$

$+e$

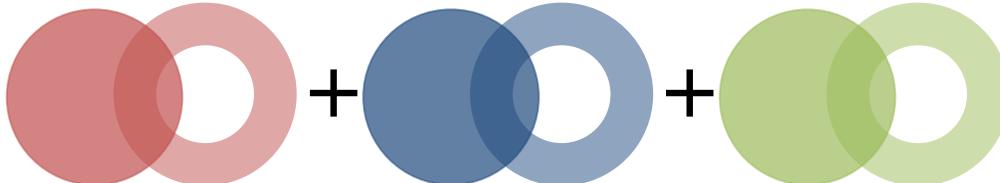

# 1. Introduction

## Color charge (review)

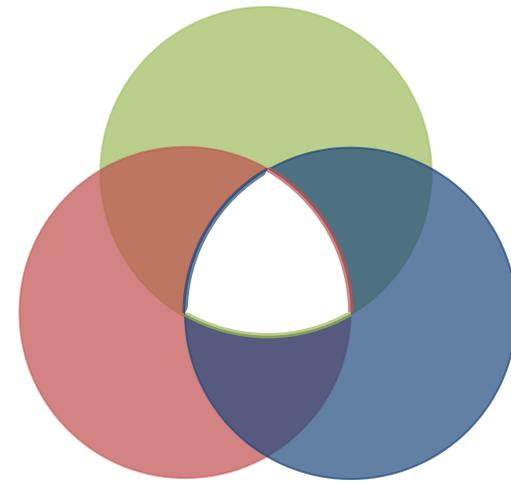

Hadrons are colorless (white:  $T_3=T_8=0$ )

meson ( $q\bar{q}$ )

$$q_r\bar{q}_r + q_g\bar{q}_g + q_b\bar{q}_b$$

baryon ( $qqq$ )

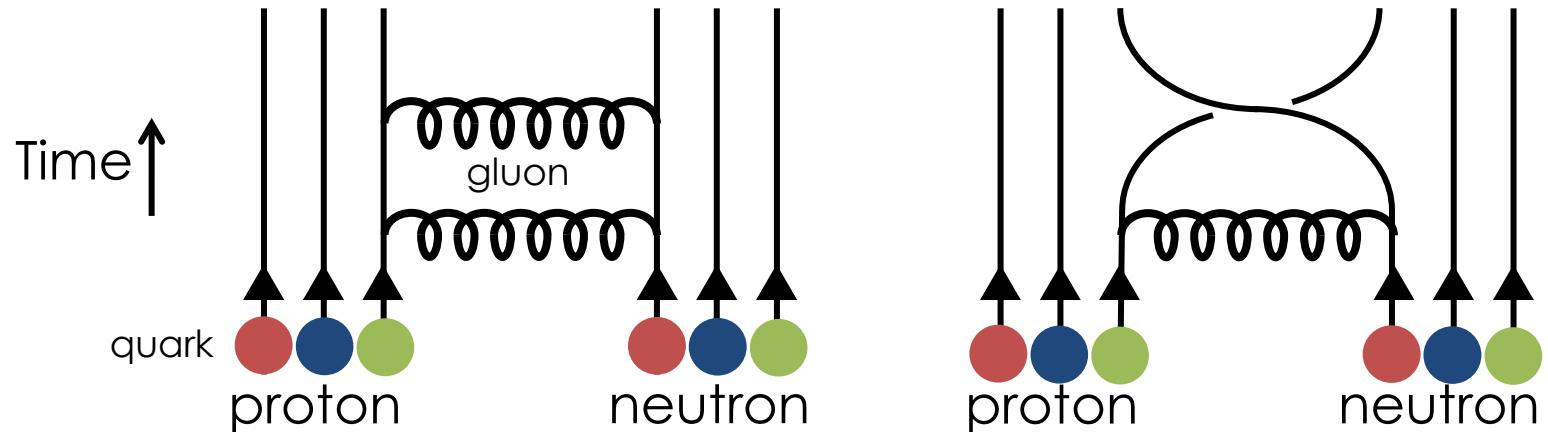

$$\epsilon_{ijk}q_iq_jq_k$$

# 1. Introduction

## Properties of QCD

- ① Color charge (red, blue, green) 
- ② Gluon exchange in inter-quark

# 1. Introduction

## Properties of QCD

- ① Color charge (red, blue, green) 
  - ② Gluon exchange in inter-quark
  - ③ Asymptotic freedom (small coupling at high energy)
  - ④ “Structure” of QCD vacuum
    - quarks are confined
    - chiral symmetry is broken
- “Big problem” in strong interaction!!**

## 1. Introduction

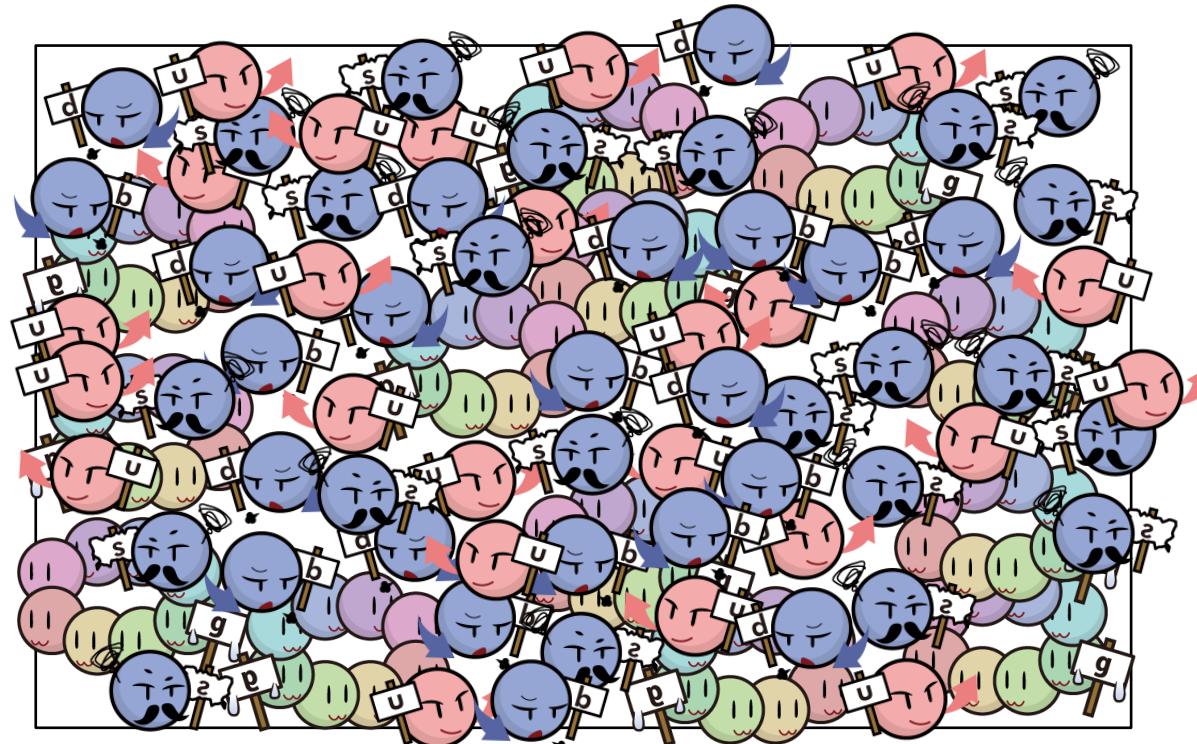

“Structure” of QCD vacuum?

Nothing?

# 1. Introduction

## “Structure” of QCD vacuum?

Many particles in QCD vacuum!

HiggsTan.com

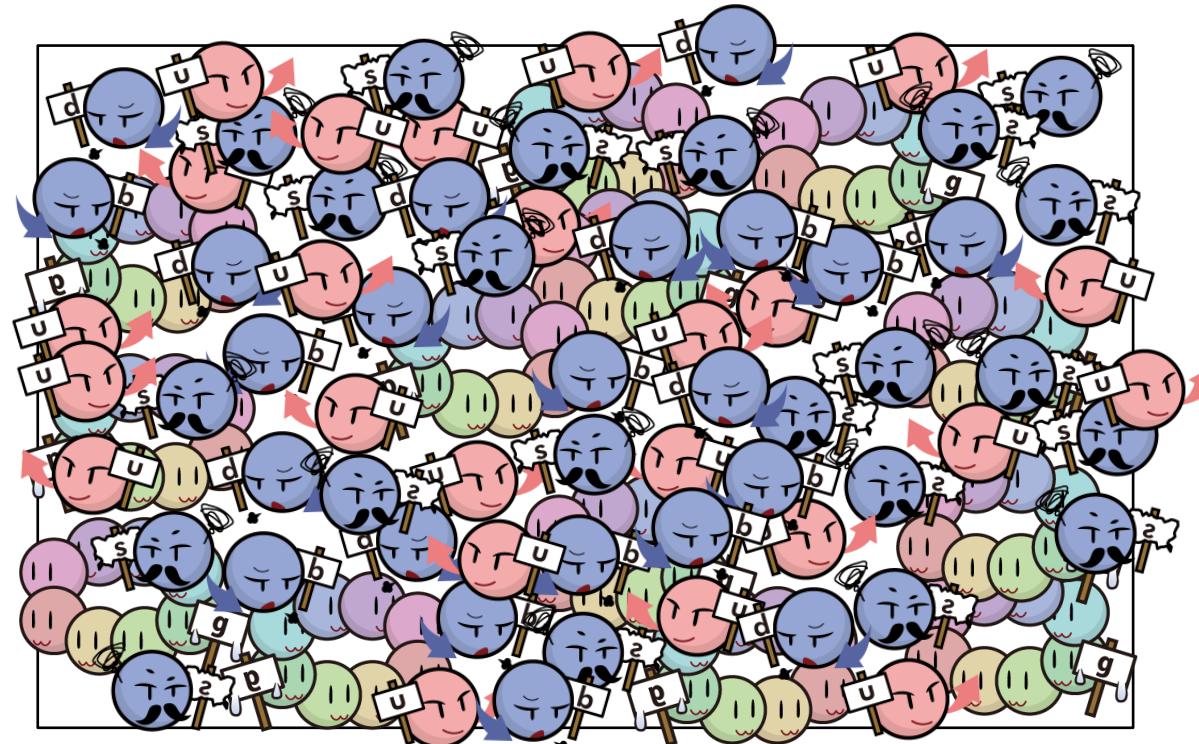

## “Non-perturbative vacuum”

(Condensate by interaction is realized by stability of energy.)

What is “exotic”?

# 1. Introduction

What is “exotic”?

1. Difference from (conventional) quark model

meson baryon

tetraquark

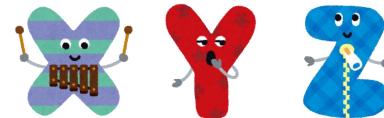

pentaquark

normal hadron

“simple”  
( $q\bar{q}$ ,  $qqq$ )

**Exotic hadron**

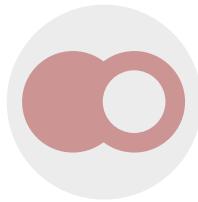

not so simple

# 1. Introduction

What is “exotic”?

## 2. Quantum numbers (charge, $J^{PC}$ )

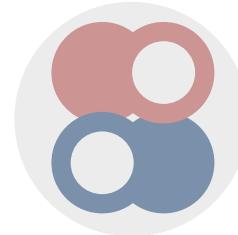

meson

$cc^{\bar{b}ar}$

tetraquark

or

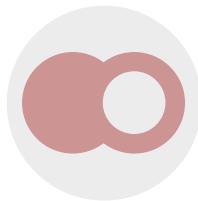

$cc^{\bar{b}ar}qq^{\bar{b}ar}$

# 1. Introduction

What is “exotic”?

## 2. Quantum numbers (**charge**, $J^{PC}$ )

meson

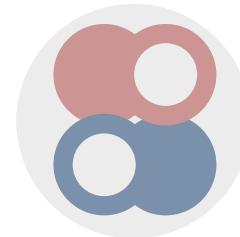

$cc^{\bar{b}ar}$

**Electric charge**

0

tetraquark

or

$cc^{\bar{b}ar}ud^{\bar{b}ar}$

+1

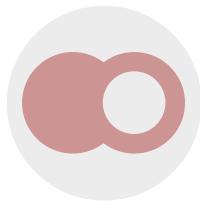

# 1. Introduction

What is “exotic”?

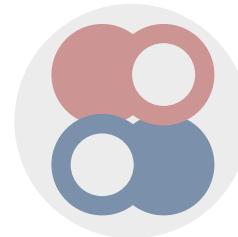

## 2. Quantum numbers (charge, $J^{PC}$ )

meson

tetraquark

or

$cc^{\bar{b}ar}$

**prohibited**

$cc^{\bar{b}ar}qq^{\bar{b}ar}$

**allowed**

**Exotic  $J^{PC}$**   
 $E^{+-}, O^{-+}$

$E=0, 2, 4, \dots$   
 $O=1, 3, 5, \dots$

# 1. Introduction

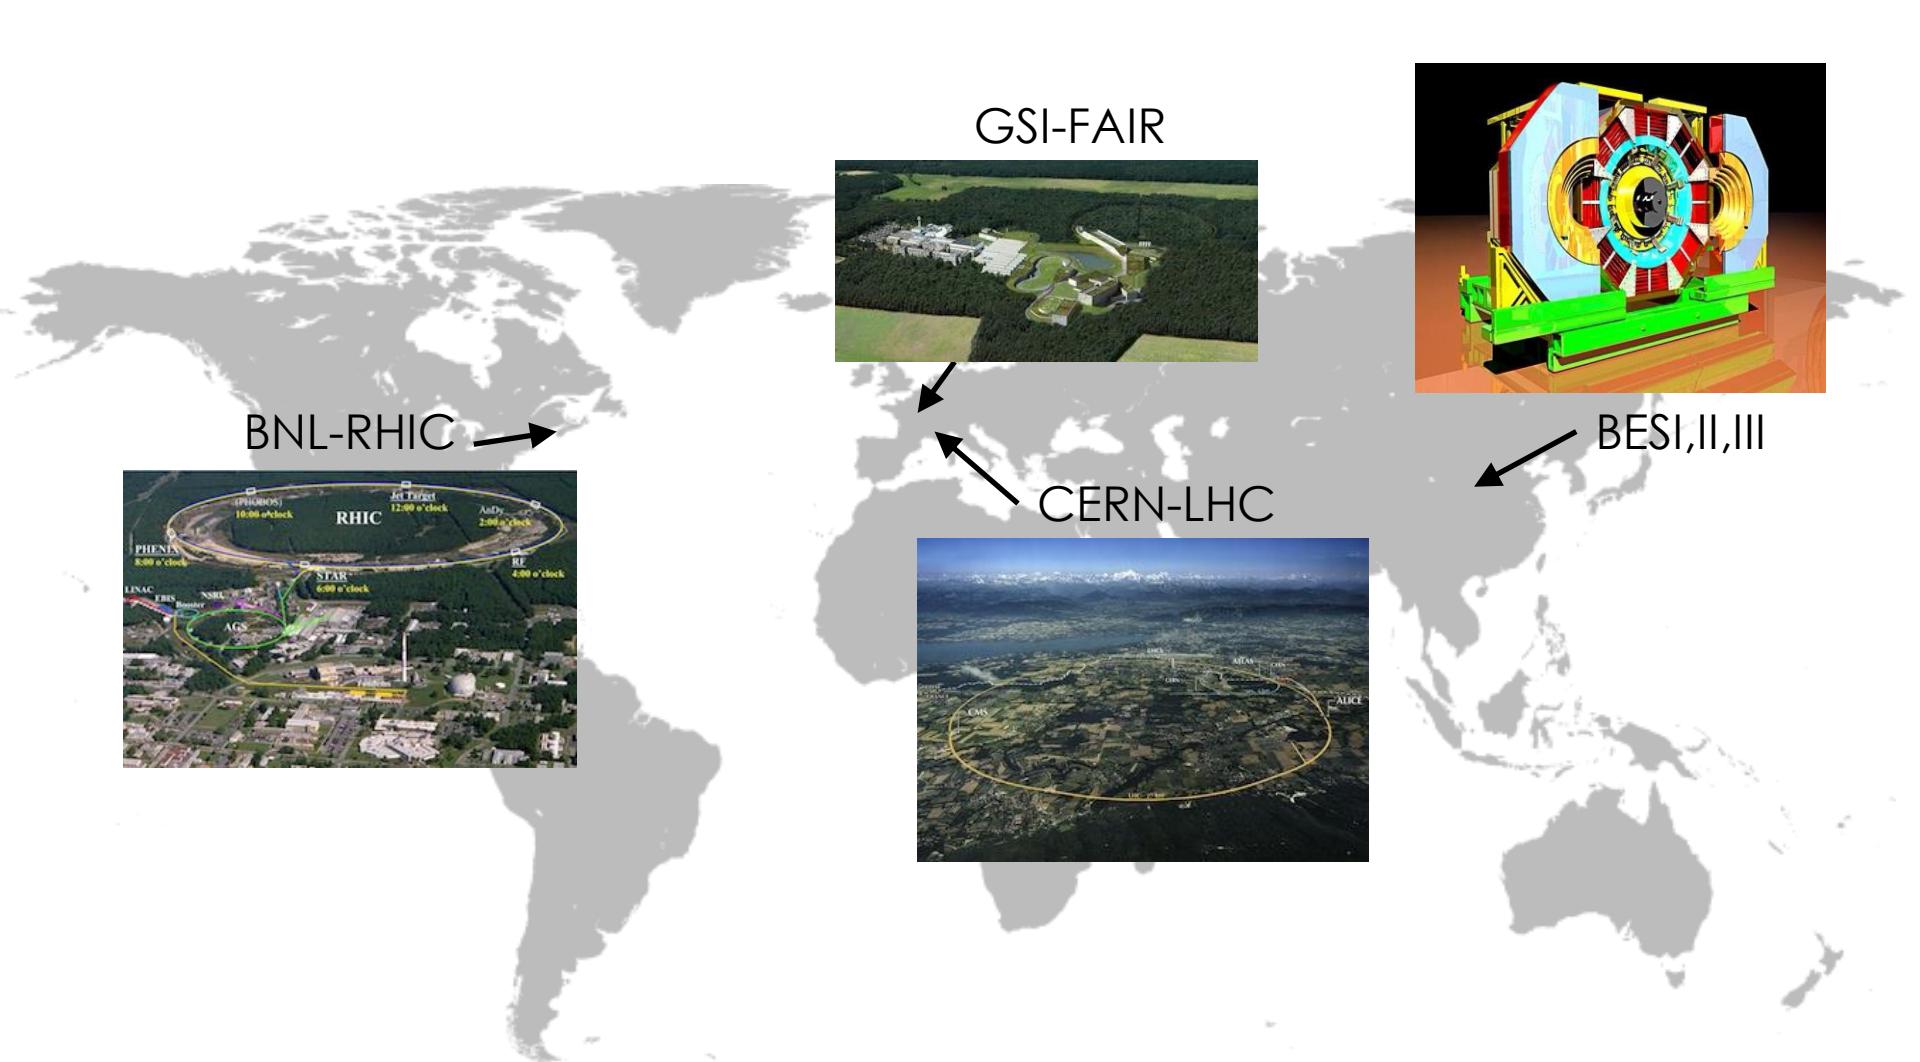

How many X, Y, Z are discovered so far?

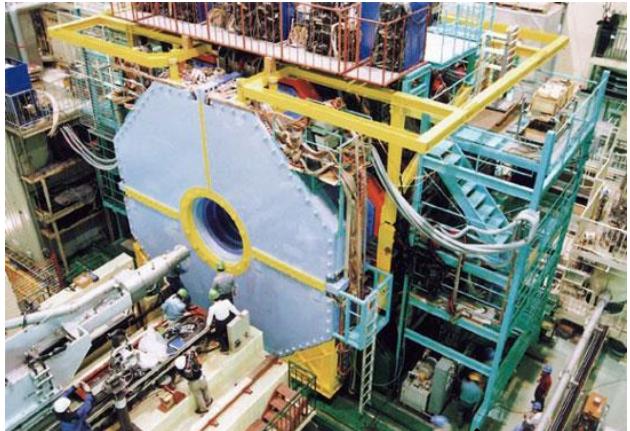

about **300**

Normal hadron  
about **300**

# 1. Introduction

How can we research exotic hadrons ?

KEK (BelleI,II)

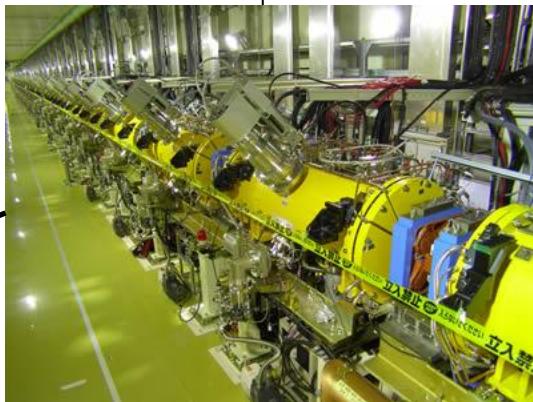

ELPH

(Resedruch Center for Electron Photon Science)

S-Pring 8  
(Super Photon ring-8 GeV)

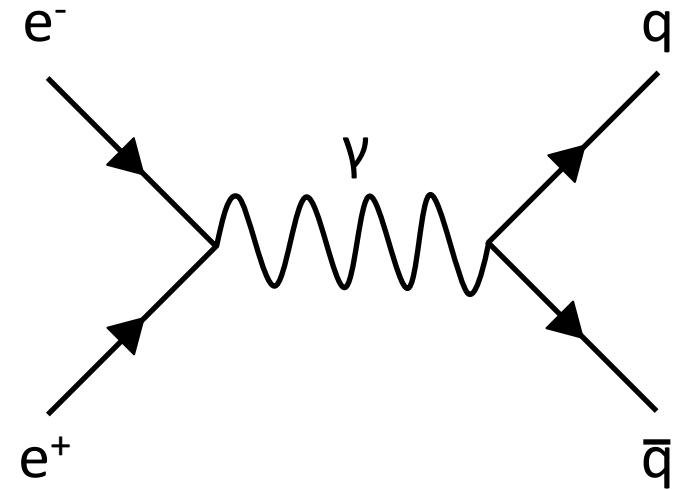

J-PARC

(Japan Proton Accelerator Research Complex)

# 1. Introduction

## Productions of exotic hadrons in Belle@KEK

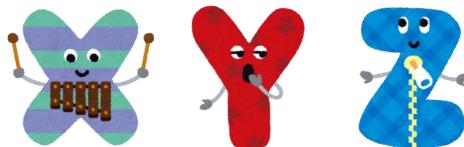

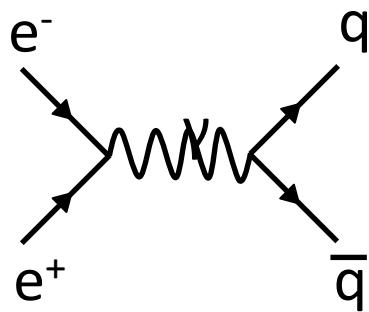

Quark-antiquark pairs are created through electron-positron collisions.

$q$  = charm, bottom

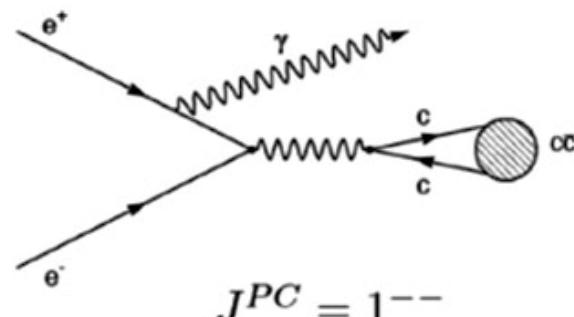

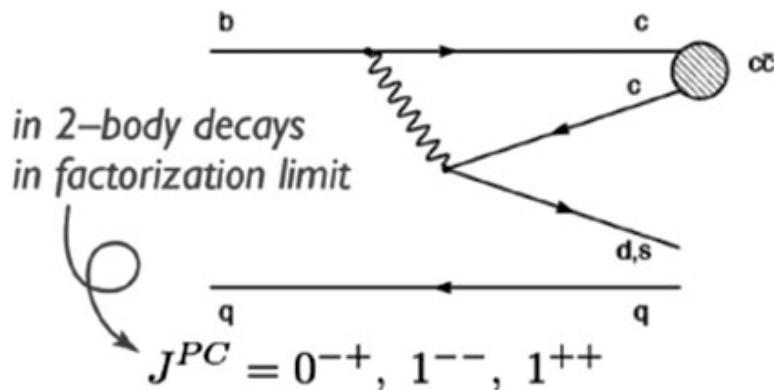

# 1. Introduction

## Variety of reactions at KEK

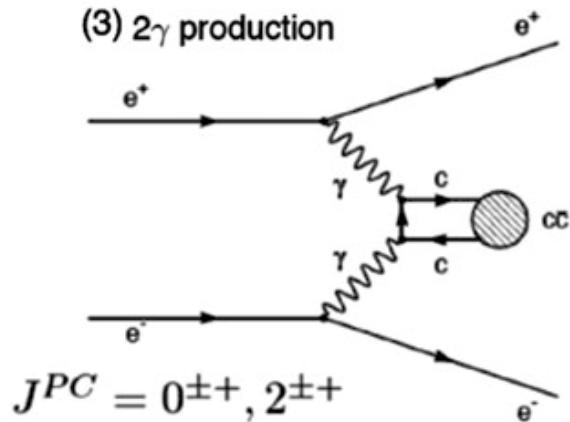

(1)  $B$  decay

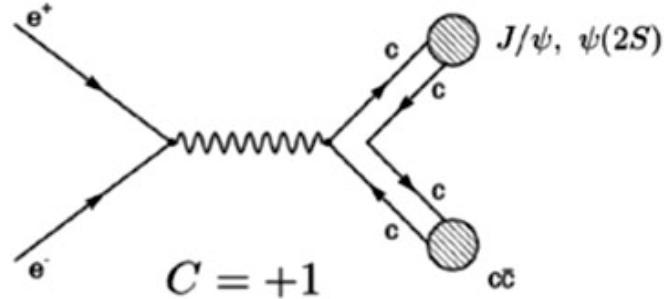

(2) Initial State Radiation (ISR)

(3)  $2\gamma$  production

(4) Double charmonium production

# 1. Introduction

## Tables of X, Y, Z discovered so far

S. L. Olsen, T. Skwarnicki, D. Ziemninska,  
Rev. Mod. Phys. 90, 015003 (2018)

quark model

number  $n_t - n_{\bar{t}}$  would be zero for all known baryons and mesons. The most interesting example of such a model is one in which the triplet has spin  $\frac{1}{2}$  and  $z = -1$ , so that the four particles  $d^-$ ,  $s^-$ ,  $u^0$  and  $b^0$  exhibit a parallel with the leptons.

A simpler and more elegant scheme can be constructed if we allow non-integral values for the charges. We can dispense entirely with the basic baryon  $b$  if we assign to the triplet  $t$  the following properties: spin  $\frac{1}{2}$ ,  $z = -\frac{1}{3}$ , and baryon number  $\frac{1}{3}$ . We then refer to the members  $u^{\frac{2}{3}}$ ,  $d^{-\frac{1}{3}}$ , and  $s^{-\frac{1}{3}}$  of the triplet as "quarks" 6) q and the members of the anti-triplet as anti-quarks  $\bar{q}$ . Baryons can now be

CERN - Geneva

In general, we would expect that baryons are built not only from the product of three uccs, AAA, but also from AAAAA, AAAAAAA, etc., where A denotes an anti-ucc. Similarly, mesons could be formed from AA, AAAA etc. For the low mass mesons and baryons we will assume the simplest possibilities, AA and AAA, that is, "deuces and treys".

### $\Lambda(uds)\Lambda(uds) \gg H(uuddss)$ hexaquark Perhaps a Stable Dihyperon\*

R. L. Jaffe†

Stanford Linear Accelerator Center, Stanford University, Stanford, California 94305, and Department of Physics  
and Laboratory of Nuclear Science,‡ Massachusetts Institute of Technology, Cambridge, Massachusetts 02139

(Received 1 November 1976)

In the quark bag model, the same gluon-exchange forces which make the proton lighter than the  $\Delta(1236)$  bind six quarks to form a stable, flavor-singlet (with strangeness of  $-2$ )  $J^P = 0^+$  dihyperon ( $H$ ) at 2150 MeV. Another isosinglet dihyperon ( $H^*$ ) with  $J^P = 1^+$  at 2335 MeV should appear as a bump in  $\Lambda\Lambda$  invariant-mass plots. Production and decay systematics of the  $H$  are discussed.

e of the most interesting candidates for a bound state is the  $H$  dibaryon, a bound state of two  $\Lambda$ 's. Although Jaffe's original calculation [2] and subsequent work [3] indicate a gain in hyperfine internal energy by recoupling color and spins in the diquark system over the two- $\Lambda$  system, a lattice calculation [4] indicates that the  $H$  is unbound well above the  $\Lambda\Lambda$  threshold. Furthermore, although hyperfine binding calculations [3] indicate the validity of the hyperfine energy to flavor-SU(3) symmetry breaking, the lattice results are insensitive to strange quark mass and SU(3) breaking [4]. A difference in the effects of SU(2) breaking

has no possibility of a quark exchange force in the lowest decay channel  $FN$  [6]. If this five-quark system breaks up into an  $F$  and a nucleon, there is no possible quark exchange between the two hadrons without flavor exchange, and therefore no diagonal matrix element of the one-gluon-exchange interaction that could give rise to a short range repulsion.

Anticharmed baryons were suggested as good candidates for possible bound exotics at the 1980 baryon conference [7]. However, the nonstrange anticharmed baryon was not bound by the hyperfine interaction and the strange anticharmed baryon was very remote from experiment and not pursued seri-

## Classical Papers of Exotic Hadrons

quarks, Gell-Mann comments that "It is amusing that the lowest baryon configuration ( $QQQ$ ) gives just the representations 1, 8, and 10 that have been observed, while the lowest meson configuration ( $Q\bar{Q}$ ) similarly gives just 1 and 8." In recent years attention has focused on developing a quark dynamics consistent with the absence of free quarks or other states of nonzero triality. The apparent spectroscopic absence of multiquark hadrons ( $Q^2\bar{Q}^2$  mesons,  $Q^4\bar{Q}$  baryons, etc.) has remained essentially where Gell-Mann left it.<sup>4</sup> Indeed, it seems foolish to attempt an explanation of the absence of exotics without at least some

*Surprisingly, we find that it is possible to accommodate  $Q^2\bar{Q}^2$  mesons relatively comfortably within the restrictions imposed by experimental meson spectroscopy.* We do not claim to resolve the problem by elevating unwanted multiquark states to very high masses. On the contrary, we will attempt to identify the lowest  $Q^2\bar{Q}^2$  multiplet, a  $J^P = 0^+$  nonet, with some of the known  $0^+$  mesons [ $\epsilon(700)$ ,  $S^*(993)$ ,  $\delta(976)$ ,  $\kappa(?)$ ]. The masses and decay systematics of the observed  $0^+$  mesons support the  $Q^2\bar{Q}^2$  assignment. Other exotics (mesons *not* classifiable as flavor octets or singlets) and cryptoexotics (flavor singlets or octets neverthe-

(Received 11 August 1981)

We discuss the existence of states made of four heavy quarks in the context of potential models already used in the study of heavy mesons and baryons. We first consider the situation where the quarks have the same mass and interact through a two-body potential due to color-octet exchange. In this case, we show that for any reasonable confining potential there is no state below the threshold corresponding to the spontaneous dissociation into two mesons. We investigate in detail different possibilities of modifying this negative result. This concerns the effect of hyperfine corrections, the case of orbitally excited states, the case of unequal quark masses, and the use of the static potential derived from the bag model treated in the adiabatic approximation.

# 1. Introduction

## Classical Papers of Exotic Hadrons

For very heavy quarks, the quark pair  $QQ$  can form a small color antitriplet object of size  $(\alpha_s(m_Q)m_Q)^{-1}$  with a binding energy of order  $\alpha_s^2(m_Q)m_Q$ . The two heavy quarks act as an almost point-like heavy color antitriplet source with a mass of

QCD contains stable four-quark  $QQqq$  hadronic states in the limit where the heavy quark mass goes to infinity. (Here  $Q$  denotes a heavy quark,  $\bar{q}$  a light antiquark and the stability refers only to the strong interactions.) The long range binding potential is due to one pion exchange between ground state  $Q\bar{Q}$ -mesons, and is computed using chiral perturbation theory. For the  $Q\bar{Q}$  QCD contains stable four-quark  $QQqq$  hadronic states in the limit where the heavy quark mass goes to infinity. (Here  $Q$  denotes a heavy quark,  $\bar{q}$  a light antiquark and the stability refers

bound states. Thus, although one cannot conclude with certainty it to be the case, this fact does favour the picture that the  $\eta(1440)$  and the  $f_1(1420)$  are mainly  $K\bar{K}^*$  composites and the  $f_0(1710)$  mainly a  $K^*\bar{K}^*$  bound state, while the

change alone is strong enough to form at least deuteronlike  $B\bar{B}^*$  and  $B^*\bar{B}^*$  composites bound by approximately 50 MeV. Composites of  $D\bar{D}^*$  and  $D^*\bar{D}^*$  states bound by pion exchange alone are expected near the thresholds, while in the light meson sector one generally needs some additional short range attraction to form bound states. The quantum numbers of these states are  $I=0$ , and  $J^{PC}=0^{-+}, 1^{++}$  for the  $P\bar{V}$  states and  $I=0$ ,

of course not quite new, but have been discussed generally only in passing within general phenomenological models for meson-meson bound states [4–14], where pion exchange is not given special attention. Recently, after my first letter [2] Ericson and Karl [15] has also studied the gluonium or “molecular multiquark” can be divided into two kinds, either models or models for bound states orons. In a recent paper [2] I suggeste the latter, or “deuteronlike meson-n pion exchange plays a dominant rôle, important, and may explain the seen c states I suggested the acronym deus
